

MAY 11-12 BRIEFINGS

You can Run, but you can't Hide Finding the Footprints of Hidden Shellcode

John Uhlmann @jdu2600

whoami

Security Research Engineer at Elastic

- Elastic Defend ("EDR") developer
- Elastic Security Labs Blogger
- https://www.elastic.co/blog/author/john-uhlmann

Agenda

- 1. Why do security products scan memory?
- 2. Memory scanning & evasion recap
- 3. Detection opportunities for hidden shellcode
- Detection via immutable code page principle violations
- Detection via CFG bitmap anomalies
- 4. Hunting via process behaviour summaries

Why do security products scan memory?

- On Windows x64, Microsoft has -
- hardened the kernel,
- claimed the hypervisor, and
- made private executable memory an indefensible boundary for kernel-mode security products.
- This just leaves memory scanning.
- It's not perfect, but it's still a valuable defensive layer.

Overview of memory scanners

Generic Scanners

- YARA memory content signatures
- PE-sieve image metadata anomalies and content heuristics
- Moneta memory metadata anomalies

Evasion recap

- Gargoyle memory protection fluctuation via APC timer and ROP chain
- obfuscate-and-sleep encrypted state fluctuation via post-sleep stub
- FOLIAGE encrypted state fluctuation via APC timers and context manipulation
- Shellcode Fluctuation memory protection fluctuation via post-sleep indirect stub
- DeepSleep memory protection fluctuation via post-sleep ROP chain
- Ekko encrypted state fluctuation via timer queues and context manipulation
- Scheduled Tasks ;-)

Evasion recap

PowePoint Slide Stow - Nyle.Newy - Nooding Manony Scanner.ppb - PoweRoat #F Reason 10.27.1.101.03.044	- 0 ×

Kyle Avery - Avoiding Memory Scanners: Customizing Malware to Evade YARA, PE-sieve, and More

https://forum.defcon.org/node/241824

Evasion – key concept

"a common technique for reducing computational burden is to limit analysis on executable code pages only" - Josh Lospinoso

https://lospi.net/security/assembly/c/cpp/developing/software/2017/03/04/gargoyle-memory-analysis-evasion.html

VirtualProtect(pShellcode, sizeof(shellcode), PAGE_READWRITE, &OldProtect);

Niche memory scanners

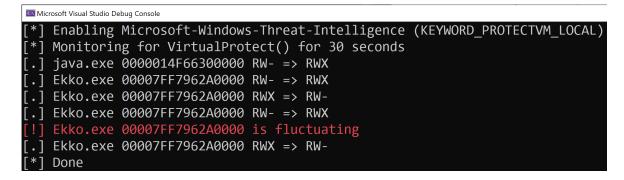

- Patriot anomalous thread CONTEXT structures
- Hunt-Sleeping-Beacons anomalous Wait call stacks
- TickTock anomalous timer-queue timers

Immutable code page principle violations

- Once code pages are written they should never change.
- The memory protection progression for code pages should only be RW to RX.
- Microsoft-Windows-Threat-Intelligence PROTECTVM_LOCAL ETW events
- IsExecutable(LastProtectionMask) && !IsExecutable(ProtectionMask)
- (Optionally) Anomalous call stack detection

An interesting discovery

Gabriel Landau

I think I just made an interesting discovery. If you VirtualAlloc(RWX), it modifies the CFG bitmap accordingly. If you then VirtualAlloc(RW), the CFG bitmap stays as-is.

Gabriel Landau

We may be able to use this to find DLL hollowing and gargoyle-style?

Control Flow Guard bitmap recap

- Time efficient lookup of valid indirect call targets
- One bitmap per process
- Each 2 bits corresponds to 16 virtual addresses
- x64 bitmap is 2TB mostly shared or reserved
- PE files bring their own bitmap
- Copied to the correct offset in process bitmap during image load
- Permissive backwards compatibility for JIT
- Memory manager simply marks all executable private addresses as valid targets

CFG bitmap anomalies

- The VAD tree only stores original protection and current protection.
- The CFG bitmap (inadvertently) records the location of all private memory addresses that are, or have previously been, executable during the lifetime of the process.
- This can be used to flag memory regions that have been changed from executable to non-executable.

🐼 Select Microsoft Visual Studio Debug Console
===== Hidden Executable Pages - scanning all processes =====
ShellcodeFluctuation.exe(912) - 1 hidden allocations
* 0000023F5F6C0000 MEM_PRIVATE
- 0000023F5F6C0000 +0x001000 RW 1/1 hidden pages

Evasion opportunities

- Protection fluctuation approaches are actually quite noisy.
- Hide your code pages in plain sight.
- Obfuscate them against current signatures ahead of time.
- Encrypt your data pages when not in use.
- Or launch in a new process every time.
- Scheduled Tasks etc.

Hunting via process behaviour summaries

Black Hat Sound Bytes

- Threat-Intelligence ETW can be used to detect violations of the immutable code page principle.
- The CFG bitmap can be used to detect shellcode hidden at a point-in-time via changed memory protections such as Gargoyle.
- Kernel telemetry can be used to construct process behaviour summaries which can be used to identify behavioural outliers for more detailed investigation.
- But, without intervention from Microsoft, private executable memory will likely remain an indefensible boundary for kernel-mode security products.
